

Project Summary Report

Sentiment Analysis on Product Reviews | Internship Week 1

Executive Overview:

This report analyses 5,000 customer reviews from the Amazon Fine Food dataset. Using Python and the TextBlob library, we processed natural language feedback to quantify customer satisfaction and identify business-critical trends.

Primary Finding: The analysis reveals a predominantly positive customer base, with 88.5% of total feedback classified as Positive.

Detailed Insights:

Customer Complaints: While the majority are satisfied, negative sentiment (approx. 10%) is primarily driven by complaints regarding packaging quality and quality of food.

Data Observations: Interestingly, some reviews with 5-star ratings were labelled as "Neutral." This occurred in reviews that were very brief (e.g., "Arrived on time") without descriptive adjectives for the model to analyse.

Strategic Recommendation:

Based on the sentiment data and qualitative review analysis, it is recommended that the business prioritizes shipping logistics and catalogue accuracy. Specifically, the company should investigate the causes of stale products resulting from extended 6-day shipping windows and audit product labelling to ensure physical dimensions like "Jumbo" match the actual item delivered. By improving delivery speed for perishable items and ensuring marketing descriptions are highly accurate, the business can eliminate specific "Negative" triggers, converting disappointed shoppers into loyal customers.
